The problem of two coupled scalar fields, one with mass much lighter than the other is analysed by means of Wilson's renormalization group approach. Coupled equations for the potential and the wave function renormalization are obtained by means of the gradient expansion. The Appelquist-Carazzone theorem is checked at energies comparable with the light mass; the physics of the light field is also studied at energies comparable and greater than the heavy mass.

It is well known that the effects on the physics of a field, due to a much heavier field coupled to the former, are not detectable at energies comparable to the lighter mass. More precisely the Appelquist-Carazzone (AC) theorem¹ states that for a Green's function with only light external legs, the effects of the heavy loops are either absorbable in a redefinition of the bare couplings or suppressed by powers of k/M where k is the energy scale characteristic of the Green's function (presumably comparable to the light mass), and M is the heavy mass. However the AC theorem does not allow to make any clear prediction when k becomes close to M and, in this region one should expect some non-perturbative effect due to the onset of new physics.

In the following we shall make use of the Wilson's renormalization group (RG) approach to discuss the physics of the light field from the infrared region up to and beyond the mass of the heavy field. Incidentally, the RG technique has been already employed to proof the AC theorem². The RG establishes the flow equations of the various coupling constants of the theory for any change in the observational energy scale; moreover the improved RG equations, originally derived by F.J. Wegner and A. Houghton³, where the mixing of all couplings (relevant and irrelevant) generated by the blocking procedure is properly taken into account, should allow to handle the non-perturbative features arising when the heavy mass threshold is crossed.

We shall discuss the simple case of two coupled scalar fields and since we are interested in the modifications of the parameters governing the light field, due to the heavy loops, we shall consider the functional integration of the

Figure 1: (a): $G_{0,2}(t)/\Lambda^2$ (curve (1)) and $10^6 \cdot G_{2,0}(t)/\Lambda^2$ (curve (2)) vs $t = \log(k/\Lambda)$. (b): $G_{2,2}(t)$ (1), $G_{0,4}(t)$ (2), $G_{4,0}(t)$ (3) vs t .

heavy field only. The action at a given energy scale k is

$$S_k(\phi, \psi) = \int d^4x \left(\frac{1}{2} \partial_\mu \phi \partial^\mu \phi + \frac{1}{2} W(\phi, \psi) \partial_\mu \psi \partial^\mu \psi + U(\phi, \psi) \right), \quad (1)$$

with polynomial W and U

$$U(\phi, \psi) = \sum_{m,n} \frac{G_{2m,2n} \psi^{2m} \phi^{2n}}{(2n)!(2m)!}; \quad W(\phi, \psi) = \sum_{m,n} \frac{H_{2m,2n} \psi^{2m} \phi^{2n}}{(2n)!(2m)!}. \quad (2)$$

Since we want to focus on the light field, which we choose to be ψ , we have simply set to 1 the wave function renormalization of ϕ . In the following we shall analyse the symmetric phase of the theory with vanishing vacuum energy $G_{0,0} = 0$.

We do not discuss here the procedure employed⁴ to deduce the RG coupled equations for the couplings in Eq. 2, because it is thoroughly explained in the quoted reference. Since it is impossible to handle an infinite set of equations and a truncation in the sums in Eq. 2 is required, we keep in the action only terms that do not exceed the sixth power in the fields and their derivatives. Moreover we choose the initial condition for the RG equations at a fixed ultraviolet scale Λ where we set $H_{0,0} = 1$, $G_{0,4} = G_{2,2} = G_{4,0} = 0.1$ and $G_{0,6} = G_{2,4} = G_{4,2} = G_{6,0} = H_{2,0} = H_{0,2} = 0$, and the flow of the various couplings is determined as a function of $t = \ln(k/\Lambda)$, for negative t .

In Fig. 1(a) $G_{0,2}(t)/\Lambda^2$ (curve (1)) and $10^6 \cdot G_{2,0}(t)/\Lambda^2$ (curve (2)) are plotted. Clearly the heavy and the light masses become stable going toward the IR region and their value at Λ has been chosen in such a way that the stable IR values are, $M \equiv \sqrt{G_{0,2}(t=-18)} \sim 10^{-4} \cdot \Lambda$ and $m \equiv \sqrt{G_{2,0}(t=-18)} \sim$

Figure 2: (a): $G_{6,0}(t) \cdot \Lambda^2$ (1), $G_{0,6}(t) \cdot \Lambda^2$ (2), $G_{4,2}(t) \cdot \Lambda^2$ (3) and $G_{2,4}(t) \cdot \Lambda^2$ (4) vs t . (b): $G_{6,0}(t) \cdot k^2$ (1), $G_{0,6}(t) \cdot k^2$ (2), $G_{4,2}(t) \cdot k^2$ (3) and $G_{2,4}(t) \cdot k^2$ (4) vs t .

$2 \cdot 10^{-7} \cdot \Lambda$. So, in principle, there are three scales: Λ , ($t = 0$), the heavy mass M , ($t \sim -9.2$), the light mass m , ($t \sim -16.1$). In Fig. 1(b) the three renormalizable dimensionless couplings are shown; the neat change around $t = -9.2$, that is $k \sim M$, is evident and the curves become flat below this value. The other four non-renormalizable couplings included in U are plotted in Fig. 2(a), in units of Λ . Again everything is flat below M , and the values of the couplings in the IR region coincide with their perturbative Feynman-diagram estimate at the one loop level; it is easy to realize that they are proportional to $1/M^2$, which, in units of Λ , is a big number. Thus the large values in Fig. 2(a) are just due to the scale employed and, since these four couplings for any practical purpose, must be compared to the energy scale at which they are calculated, it is physically significant to plot them in units of the running cutoff k : the corresponding curves are displayed in Fig. 2(b); in this case the couplings are strongly suppressed below M .

It must be remarked that there is no change in the couplings when the light mass threshold is crossed. This is a consequence of having integrated the heavy field only: in this case one could check directly from the equations ruling the coupling constants flow, that a shift in the initial value $G_{2,0}(t = 0)$ has the only effect (as long as one remains in the symmetric phase) of modifying $G_{2,0}(t)$, leaving the other curves unchanged. Therefore the results obtained are independent of m and do not change even if m becomes much larger than M . An example of the heavy mass dependence is shown in Fig. 3(a), where $G_{6,0}(t)$ is plotted, in units of the running cutoff k , for three different values of $G_{0,2}(t = 0)$, which correspond respectively to $M/\Lambda \sim 2 \cdot 10^{-6}$, (1), $M/\Lambda \sim 10^{-4}$, (2) and $M/\Lambda \sim 0.33$, (3). Note, in each curve, the change of slope when the M scale is crossed. $H_{0,0} = 1$, $H_{0,2} = 0$ is a constant solution of the

Figure 3: (a): $G_{6,0}(t) \cdot k^2$ vs t for $M/\Lambda \sim 2 \cdot 10^{-6}$ (1), $\sim 10^{-4}$ (2), ~ 0.33 (3). (b): $H_{2,0}(t) \cdot k^2$ for the three values of M/Λ quoted in (a).

corresponding equations for these two couplings; on the other hand $H_{2,0}$ is not constant and it is plotted in units of the running cutoff k in Fig. 3(b), for the three values of M quoted above.

In conclusion, according to the AC theorem all couplings are constant at low energies and a change in the UV physics can only shift their values in the IR region. Remarkably, for increasing t , no trace of UV physics shows up until one reaches M , that acts as a UV cut-off for the low energy physics. Moreover, below M , no non-perturbative effect appears due to the non-renormalizable couplings that vanish fastly in units of k . Their behavior above M is somehow constrained by the renormalizability condition fixed at $t = 0$, as clearly shown in Fig. 3(a) (3). Finally, the peak of $H_{2,0}$ at $k \sim M$ in Fig. 3(b), whose width and height are practically unchanged in the three examples, is a signal of non-locality of the theory limited to the region around M .
